**ABSTRACT**

To facilitate recognition of cultural units of measure associated with Euroamerican archaeological remains in North America, knowledge of historic measurement systems commonly used by Euroamericans is essential. For Canadian research, specific systems used in England, France, America and Canada during the 15th - 19th centuries provide a comprehensive view of the plethora of measurement units in common use. Measurement units constituting these systems are systematically organized by country, type of measurement system and period of usage.

To facilitate commercial research of archaeological remains in Canada, a compilation of the major legislative statutes governing the use of weights and measures provides a glimpse of measurement customs and regulations which governed commerce during the 17th - 19th centuries.

To facilitate future research within archaeological metrology, six inferences of metrological systems, units and archaeological remains are inferred from observations of historic measurement systems, suggesting a few of the more relevant correspondences among systems, units and surviving remains.

Submitted for publication 1980, by Lester A. Ross, Parks Canada, Ottawa.

#### ACKNOWLEDGEMENTS

In conducting research for this work, extensive use was made of special reference collections at the Yale Medical Library and the National Library of Canada. I express my sincere appreciation to Ferenc Gyorgyey and his staff at the Yale Medical Library, and to John Streeter, who provided assistance and guidance in the use of the Edward Clark Streeter reference library on historic weights and measures. My appreciation is also extended to archivists Betty Deavy and Bill Murphy of the National Library of Canada, and to librarian Michael Graham of the Library of Parliament, for their cooperation and assistance in locating copies of the numerous laws and statutes pertaining to the adoption of weights and measures within Canada and its provinces.

## INTRODUCTION

*Jack and Jill went up the hill  
To fetch a pail of water.  
Jack fell down and broke his crown,  
And Jill came tumbling after.  
(Klein 1974:39)*

The Greeks had a word for it - *metrologia* - denoting the theory of ratios. In our present age, metrology denotes the study of systems of weights and measures. For many non-literate societies, weights and measures appear to be idiosyncratic or communal, while among commercially oriented and literate societies, weights and measures tend to be societal, regional and national. Literate societies also attempt to standardize and codify metrological systems for the explicit goal of regulating trade. For such societies, research on past systems tends to be historical, but as one well-known classical archaeologist came to recognize, many historical metrological systems were either never historically recorded or their records of existence have subsequently been lost.

At the 9 April 1878 meeting of the Anthropological Institute of Great Britain, William Flinders-Petrie read a paper on inductive metrology in which he defined his subject as the deduction of ancient units of measure from measurements of existing archaeological remains of both historic and prehistoric architectural features (Nature 1878). One year earlier, Flinders-Petrie (1877) published his initial work on inductive metrology and through his lifelong work on pharaonic Egyptian archaeology he consistently demonstrated the value of historical and archaeological metrology for the description and interpretation of architectural and commercial remains (e.g. Flinders-Petrie 1926, 1931). Flinders-Petrie noted that cultural units of measure were easily discernible from surviving architectural remains, and argued that such units should be explicitly sought with the goal of defining ancient systems of linear measure.

Extending Flinders-Petrie's primary goal, archaeologists should seek to define culturally significant metrological units and systems for all categories of material culture, not just architectural structures. Within the anthropological and archaeological disciplines, one commonly held belief is that mankind produces material culture according to preconceived mental templates. As such, items are manufactured to meet pre-existing material, functional, stylistic and metrological requirements. Thus, the manufacture of a lithic projectile point by a pre-literate knapper may be subjected only to material, functional and stylistic requirements, while the manufacture of a firearm cartridge must also meet rigorous requirements of size and mass.

Archaeological research of material culture generally requires size determination, occasionally for interpretive purposes, but more often only for descriptive purposes. Archaeologists have a penchant for discovering statistically meaningful sizes, but rarely are such research

sizes related to cultural units and systems. In measuring artifacts, archaeologists attempt to discover valid sizes which have some significance for interpretive conclusions. Complete measurements are taken in order to define absolute size variability and relative size comparisons which may be useful for research purposes (Figure 1). Once an absolute size, with its variability, has been defined, partial artifact measurements can also serve to help identify research sizes. Normally, researchers generate size information for the purpose of demonstrating stylistic variability within an artifact class. Occasionally, however, sizes are compared to cultural measurement units in an attempt to document an historical interpretation; but rarely are attempts made to document or reconstruct cultural measurement systems.

Cultural measurement systems consist of two basic classes of systems - relative and metrological (or absolute) systems (e.g. Figure 2). Relative systems attempt to size material according to a hierarchy of relative units which are vaguely defined in relation to one another. For example, British clothing merchants used the unit *vest button* to signify the size of a button larger than a *shirt button* but smaller than a *brace button* (Figure 2). The actual metric size of a *vest button* probably had a wide range of variability, and may have overlapped in size with both *shirt* and *brace buttons*.

Metrological systems, however, attempt to size material according to a mathematical scale of multiple units which are more or less precisely defined according to a standard unit of measure and which generally share one or more common ratios of relationship to one another. For example, American clothing merchants used the metrological unit of a *line* (0.635 mm) to measure button sizes, with sizes ranging between 8-50 *lines*. In this instance of a metrological system, only one metrological unit was required, and sizes were designated by a mathematical ratio of even-numbered *lines*.

For these two basic classes of cultural measurement systems there are seven types of systems classified within three groups defined by the standards used to define each system (Table 1).

Table 1. Types of cultural measurement systems classified according to standards used to define each system.

System Standards	Types of Measurement Systems
Mass Standards	Dry Weight Systems Liquid Weight Systems
Capacity Standards	Dry Capacity Systems Liquid Capacity Systems
Linear Standards	Linear Systems Superficial Systems Volumetric Systems

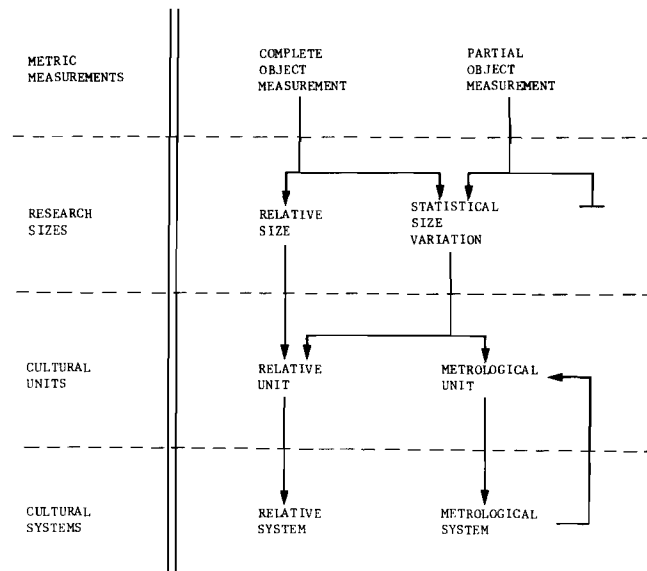

Figure 1. Relationships among material culture measurements, postulated sizes, cultural units and systems of weights and measures for archaeological research.

a) British Clothing Button Sizes

Shirt  
Vest  
Brace  
Jacket  
Coat  
Overcoat

b) American Clothing Button Sizes (8-50 *lines*)

Figure 2. Examples of relative vs. metrological cultural systems for sizing 19th-century clothing buttons: a) relative cultural system used by British merchants (Ross 1976: 1380) and b) metrological cultural system, based upon a culturally unidentified line measuring 0.57 mm, used by American merchants (Montgomery Ward & Co. 1895: 85).

Standards applied to systems within a single group represent primary standards while standards associated with systems from one group and applied to systems within another group represent secondary standards. Thus, a capacity standard used to define dry or liquid capacity systems is a primary standard, but when used to define a dry weight system it becomes a secondary standard. For example, the *bushel* used to define wheat capacity in England during the 15th century would be regarded as a primary standard for the Henry VII Winchester Corn Capacity System, but when it was used to define wheat weight as in the Henry VII Winchester Corn Weight System it functioned as a secondary standard. According to the definition of wheat weight used by Henry VII, a *bushel* of wheat weighed  $66 \frac{2}{3}$  *Troy pounds*. For the dry weight system, the *Troy pound* was the primary standard, while the weight of a *bushel* of wheat from the dry capacity system was the secondary standard.

Reliance upon mass, capacity and linear standards for various types of measurement systems is paramount and must be both explicitly understood and well defined in order to reconstruct historic cultural systems from existing artifact measurements. When research measurements are taken according to a linear standard, they must be converted to a capacity standard in order to reconstruct a capacity system. Likewise, standards used to measure artifacts must be well known and convenient to work with so that discrete cultural units and ratios of such units can be easily recognized by the researcher. To facilitate the collection, manipulation and interpretation of metrological data the basic standards to be employed in research are metric weight, capacity and linear units. Converting from these units to other cultural units has become recognized as the accepted method for all metrological research, and the tables forming the body of the following report have been established to facilitate such conversions.

Prior to initiating the reconstruction of historical units and systems of measurement, it is desirable to have access to all available historic systems pertaining to the culture in question. For North American historical archaeologists working with European material culture, it would be desirable to have access to a resource document listing all European and North American measurement systems used during the 15th through 20th centuries. Such a document is non-existent, but in an attempt to partially remedy this problem, information has been compiled for many of the more common English, French, American and Canadian systems in use during the 15th through 19th centuries. These systems have been identified from various published sources, and have been arranged by country, type of measurement system and period of use. This collection of systems is far from complete, but it should serve as a basic guide to the major systems represented in North America. Through subsequent research it is hoped that specific systems used for various classes of material culture may be explicitly identified, such as the button systems mentioned previously, and such as the systems used for glass beads, nails, ceramics and glass vessels, etc. Through such research, the goal is to demonstrate the significance of metric data for deriving cultural and temporal ascriptions, and for identifying and describing unrecognized historic systems of measurement. Perhaps with the publication of the following collected work of known historical

systems of measurement, other researchers will be encouraged to analyze their metric data with similar goals in mind - such at least is the hope.

## ENGLISH SYSTEMS OF WEIGHTS AND MEASURES

Unlike the French systems of weights and measures, English systems were primarily based upon national systems enacted in law by the Crown. There were also city and county systems, but their usage was officially discouraged by the use of regional inspectors who possessed "exact" copies of royal metrological standards. Through use, these comparative standards often became inaccurate copies of original standards which only approximated the true metrological units of their systems. However, the use of these regional inspectors and gaugers did help alleviate regional variability for national and international commerce, and this national uniformity should be reflected by English material culture.

### Dry Weight Systems

Of the 29 English dry weight systems identified (Table 2), seven can be regarded as systems of major importance (Figure 3); three presumed systems, based upon secondary dry capacity standards and probably used in the weighing of wheat, were of insignificant importance for the weighing of other commercial commodities; and the remaining 19 systems were based upon the seven major systems.

The two primary standards for the seven major systems were the *wheat* and *Troy grains* of 0.04556 g and 0.0648 g, respectively. These standards were physically embodied within each dry weight system by a larger unit known as a *pound*, with each *pound* being identified by the total number of *wheat* and/or *Troy grains* it contained. Unfortunately, few *pound* standards survived into more recent times, thus denying modern scholars an opportunity to check the accuracy of earlier systems. In fact, the question of weight variability for *wheat* and *Troy grains* through time has never been completely addressed, and it is highly likely that physical *pound* standards maintained by the Crown and various merchant guilds varied considerably in relationship to their mathematical counterparts. From this observation it is inferred that metrological systems identify mathematical relationships among metrological units, but the physical units of a system will not always equate in size or mass with their corresponding metrological units.

Thus, metric weights given in the following tables must be regarded as approximate weights which undoubtedly varied within the real marketplace. For comparative historical archaeological purposes, recognition of the relative weight ratios among the seven major systems is essential. The *Tower pound* was the lightest of all, with the *Haverdepoise pound* being the heaviest (Table 3).

Table 2. English dry weight systems and their known period of usage  
 (\*presumed system).

ENGLISH DRY WEIGHT SYSTEMS	PERIOD IN USE
Tower Pound	791 - 1527
Merchants' Pound	1266 - 1527
Hanseatic Merchants' Pound	pre-13th C - 1582
Avoir-du-pois Pound	1340 - 1582
Avoir-du-pois Wool	
Avoir-du-pois Hay	
Avoir-du-pois Coal	
Haverdepoise Merchants' Pound	1497 - 1582
Henry VII Winchester Corn*	1497 - 1601
Troy Pound	1497 - 20th C
Troy Corn	
Troy Imaginary Mint	
Troy Pound Carat	
Troy Ounce Carat	
Jewellers'	
Apothecary	
Avoirdupois Pound	1582 - 20th C
Avoirdupois Wool	
Avoirdupois New Hay	
Avoirdupois Old Hay	
Avoirdupois Straw	
Avoirdupois Coal	
Avoirdupois Salt	
Avoirdupois Lead	
Avoirdupois Stannary	
Avoirdupois Gunpowder	
Avoirdupois Glass	
Elizabeth I Winchester Corn*	1601 - 1702
William III Winchester Corn*	1702 - 1826

Figure 3. Comparison of the major English dry weight systems and their period of usage (post-1400).

Table 3. Comparison of weights among the seven major English dry weight *pounds* in use during the 15th through 19th centuries.

ENGLISH DRY WEIGHT POUNDS	TROY POUNDS	GRAMS
<i>Tower Pound</i>	5400	349.92
<i>Troy Pound</i>	5760	373.248
<i>Merchants' Pound</i>	6750	437.40
<i>Avoir-du-pois Pound</i>	6992	453.0816
<i>Avoirdupois Pound</i>	7000	453.60
<i>Hanseatic Merchants' Pound</i>	7200	466.56
<i>Haverdepoise Pound</i>	7680	497.664

Utilizing these relative weight relationships among the seven major systems, artifacts can be weighed and compared to expected weights in order to postulate original cultural metrological units. For example, if an axe head found within a 19th-century context weighed 1810 g, it could be postulated that on the basis of its weight alone, the axe head was manufactured in a country using the Avoirdupois Pound Weight System, since its weight corresponds to four *Avoirdupois pounds*. For Canadian historical archaeological sites, this comparative approach could be used to distinguish material culture manufactured by English vs. French tradesmen. Similar examples of weight variations for material culture could also assist in the ascription of the temporal period of manufacture and in the identification of specific dry weight systems used in the manufacture of specific classes of commodities. From these observations, it is inferred that object measurements used to identify metrological units and systems can also be utilized to ascribe both cultural and temporal affiliations.

## TOWER POUND WEIGHT SYSTEM (791 - 1527)

The *Moneyer's* or *Saxon pound* (791 - 1066) or *Moneyer's Tower pound* (1066 - 1527) was defined by Offa, Anglo-Saxon King of Mercia (757 - 796) in 791 on the basis of the *Arabic silver half dirhem* of 22-23 *grains* and officially abolished in 1527 by Henry VIII. The *Tower pound* was incorrectly identified as a *Troy pound* on a 1746 broadside purportedly taken from the Table of Standard Weights and Measures of the Exchequer for 1497 (Standard... 1746). This table was prepared from weights given in Skinner 1967 and Zupko 1977: 11 and 78. NOTE: The modern *grain* of amber durum wheat weighs between 0.0421-0.0439 g (Canadian Grain Commission 1978).

**MERCHANTS' POUND WEIGHT SYSTEM (in Britain, 1266 - 1527)**

The *Merchants' pound* was in use among southern German cities and was officially enacted in Britain in 1266 by Henry III and abolished in 1527 by Henry VIII. This table was prepared from weights given in Skinner 1967 and Zupko 1977.

**HANSEATIC MERCHANTS' POUND WEIGHT SYSTEM (in Britain, pre-13th century - 1582)**

The *Hanseatic Merchants' pound* was in use among northern German and Baltic coastal cities prior to its use by the Hanseatic merchants of London during the 13th century. It was officially replaced in 1582 by Elizabeth I. This table was prepared from weights given in Moody 1960, Skinner 1967 and Zupko 1977.

AVOIR-DU-POIS HAY WEIGHT SYSTEM (1352 - 1582)

This presumed system was based upon the *Avoir-du-pois pound* established in 1352 and replaced in 1582, and was used in the national commerce of hay. This table was prepared from weights given in Zupko 1977: 156.

METRIC

453.0816 g		1	<i>Avoir-du-pois Pound</i>		
25.3726 kg	56	1	<i>Truss</i>		
913.412 kg	2016	36	1	<i>Load</i>	

AVOIR-DU-POIS COAL WEIGHT SYSTEM (1352 - 1582)

This hypothesized system may have been established when the *Avoir-du-pois pound* was officially defined in 1352. Zupko (1977: 151) stated that an "Avoirdupois" coal system was in use 1421 - 1676. However, the *Avoirdupois pound* was not adopted until 1582, so an earlier system based upon the older *Avoir-du-pois pound* may have existed.

## HENRY VII WINCHESTER CORN WEIGHT SYSTEM (1497 - 1601)

This presumed system is based upon the *bushel* and *gallon* dry capacity standards measuring 2144.81 *cubic inches* and 268.43 *cubic inches*, respectively, established by Henry VII in 1497. According to Statute 12 Henry VII 1496, a *pint* of wheat was equal to an eighth *gallon* and weighed 12 1/2 *Troy ounces*. This system was altered with the development of the new *bushel* and *gallon* standards of Elizabeth I. This table was prepared from weights given in Skinner 1967: 100, 105.

### TROY POUND WEIGHT SYSTEM (1497 - present)

The *Troy pound* was in use in Britain by at least 1414 and was officially adopted by Henry VII in 1497 for precious metals, coinage and bread. The system continues in use to this day, albeit minus those units greater than the *Troy ounce* which were abolished by the Weights and Measures Act of 1878. This table was prepared from weights given in Standard... 1746, Good et al. 1813, Irwin 1960, Moody 1960, Skinner 1967, Dresner 1972 and Zupko 1977.

### AVOIRDUPOIS POUND WEIGHT SYSTEM (1582 - present)

The *Avoirdupois pound* of 7000 grains was established in 1582 by Elizabeth I to replace the two remaining *Merchants' Pound* systems still in use in Britain (i.e. the *Avoir-du-pois* and *Haverdepoise* pound systems). In 1840 the *Avoirdupois pound* was given as 453.544123364 g (Doursther 1840: 214), but the British standard weighed in 1844 was found to be 453.59265 g (Judson 1976: 17). This table was prepared from weights given in Good et al. 1813, Doursther 1840, Irwin 1960, Moody 1960, Skinner 1967, Dresner 1972 and Judson 1976.

ELIZABETH I WINCHESTER CORN WEIGHT SYSTEM (1601 - 1702)

This presumed system was based upon the *bushel* and *gallon* capacity standards measuring 2148.28 *cubic inches* and 268.97 *cubic inches*, respectively, established by Elizabeth I in 1601 as replacements for the standards established in 1497 by Henry VII. Based upon the bulk densities of wheat as calculated from the standards of Henry VII, these hypothesized *bushel* and *gallon* corn weights were 0.2% and 0.16% greater than those of Henry VII. Elizabeth's standards were replaced in 1702 by William III. Skinner (1967: 105) noted that a second *gallon* capacity standard of 270.59 *cubic inches* made during the reign of Elizabeth I was incorrectly regarded in 1758 as the primary standard. This presumed system follows the weight units defined by Henry VII.

## WILLIAM III WINCHESTER CORN WEIGHT SYSTEM (1702 - 1826)

This presumed system was based upon the *bushel* capacity standard measuring 2150.42 *cubic inches* established by William III in 1702 as a replacement for the *bushel* and *gallon* capacity standards established by Elizabeth I in 1601 (Skinner 1967: 105). Based upon the bulk densities of wheat as calculated from the standards of Henry VII, the *bushel* corn weights of William III was 0.1% greater than that for Elizabeth I and 0.26% greater than that for Henry VII. This system was abolished with the adoption of the Imperial system. This presumed system follows the weight units defined by Henry VII.

## Liquid Weight Systems

Only two English liquid weight systems were utilized, and both were defined on the basis of secondary standards taken from liquid capacity systems (Table 4). Both systems were used exclusively in the commerce and dispensing of liquid medicines.

Table 4. English liquid weight systems, their known period of usage, and their standard *gallon* weights.

ENGLISH LIQUID WEIGHT SYSTEMS	PERIOD OF USE	GALLON (g)
Winchester Wine Apothecary	pre-1707 - 1826	3779
Imperial Apothecary	1826 - ?	4536

## WINCHESTER WINE APOTHECARY LIQUID WEIGHT SYSTEM (pre-1707 - 1826)

This system was based upon the Queen Anne Winchester *wine gallon* measuring 231.0 *cubic inches* holding approximately eight *Hanseatic Merchants' pounds* of water. The origins of this system remain unknown, but it would appear to have existed prior to the abolition of the *Hanseatic Merchants' pound* in 1522. This system was used to weigh liquid pharmaceuticals and was abolished with the adoption of the Imperial system (Phillips 1848).

### Dry Capacity Systems

Of the five English dry capacity systems identified, four can be regarded as major systems, with the one remaining system being based upon one of the four major systems (Table 5).

Table 5. English dry capacity systems, their known period of usage, and their standard *gallon* and *bushel* capacities.

ENGLISH DRY CAPACITY SYSTEMS	PERIOD OF USE	GALLON (1)	BUSHEL (1)
Henry VII Winchester	1497 - 1601	4.398	35.145
Elizabeth I Winchester	1601 - 1702	4.407	35.202
William III Winchester	1702 - 1826	4.405	35.237
Imperial	1826 - 20th C	4.543	36.348
Imperial Coal			

The *gallon* and *bushel* standards for the Henry VII and Elizabeth I Winchester Corn Capacity systems did not mathematically equal the 1:8 ratio expressed within their systems. In each system the *gallon* capacity was slightly greater than its corresponding one-eighth *bushel* capacity. Thus, the *Henry VII Winchester gallon* was 0.12% greater and the *Elizabeth I Winchester gallon* was 0.16% greater than their corresponding one-eighth *bushel* capacities. From this observation it is inferred that metrological unit standards may not equate with related unit standards within the same metrological system.

The Winchester capacity systems were originally designed to measure wheat (i.e. what the English refer to as "corn"), but any dry commodity could be similarly measured. The various Winchester *gallon* and *bushel* measures were also used as primary standards for liquid capacity, and possibly as secondary standards for dry weight, systems. The Imperial Dry Capacity System was based upon a standard defined in terms of the cubic capacity of a given weight of water, and thus this dry capacity system is partially based upon a secondary standard of mass. From these observations it is inferred that metrological units and systems designed for one type of measurement system can also be used for other types of measurement systems.

## HENRY VII WINCHESTER CORN CAPACITY SYSTEM (1497 - 1601)

This system was based upon the *bushel* and *gallon* standards measuring 2144.81 *cubic inches* and 268.43 *cubic inches*, respectively, established by Henry VII, and replaced by Elizabeth I. This table was prepared from capacities given in Skinner 1967: 105.

### IMPERIAL DRY CAPACITY SYSTEM (1826 - present)

This system was defined by an act of Parliament in 1824, and officially adopted 1 January 1826. The *Imperial gallon* was to be that volume equal to 10 *Avoirdupois pounds* of distilled water weighed in air at the temperature of 62° F at a barometric pressure of 30 inches of mercury. It was further defined as 277.274 *cubic inches*, but in 1931-32 this capacity was correctly determined as 277.421 *cubic inches*. This table was prepared from capacities given in Doursther 1840, Loudon 1871 and Skinner 1967.

### Liquid Capacity Systems

Of the nine English liquid capacity systems identified, eight can be regarded as major systems, with the one remaining system being based upon one of the eight major systems (Table 6).

Table 6. English liquid capacity systems, their known period of usage, and their standard *gallon* capacities.

ENGLISH LIQUID CAPACITY SYSTEMS	PERIOD OF USE	GALLON (1)
Henry III Merchants' Wine	1266 - 1707	3.670
Henry VII Winchester Wine and Ale	1497 - 1601	4.398
Elizabeth I Winchester Wine and Ale	1601 - 1826	4.407
Queen Anne Winchester Wine	pre-1707 - 1826	3.785
Ale	? - 1803	4.621
Beer	? - 1826	4.621
Ale and Beer	1688 - 1803	?
Imperial	1826 - 20th C	4.455
Imperial Culinary		-

The earlier systems were established in order to regulate the trade in fermented beverages, but they were also used to measure any commercial liquid. As can be seen in Table 4, the *gallon* capacities of these systems varied between 3.670-4.621 l; and as many as seven systems could have been in cultural use simultaneously. In 1707, Queen Anne attempted to codify one of the existing *gallon* standards as the official unit of liquid measure, but because of its relatively small size, this unit did not replace the larger *gallon* units commonly used in beer and ale commerce. In 1826, with the adoption of the Imperial standard, a single uniform *gallon* standard was again codified, but it required many generations for the Imperial Liquid Capacity System to totally replace the Queen Anne Winchester Wine Gallon System. From this observation it is inferred that for any given type of measurement system (e.g. liquid capacity, liquid weight, dry capacity, etc.), multiple metrological systems can be simultaneously employed by a society, reflecting either contemporaneous usages for measuring multiple commodity classes, or anachronistic usages for measuring a single commodity class, presumably reflecting idiosyncratic-communal preferences which are regionally derived.

### HENRY III MERCHANTS' WINE GALLON SYSTEM (1266 - 1707)

This hypothetical system was based upon the *Merchants' pound* of 15 *Tower ounces* with a *gallon* equalling eight *Merchants' pounds* of wheat as decreed by Henry III Royal Ordinance of 1266. Skinner (1967: 93) hypothesized that eight *Merchants' pounds* of wine would have given a *gallon* capacity of 216 *cubic inches*, but he observed that no such standard was ever noted. Berriman (1953: 163) noted that in 1688 the Guildhall of the City of London used a *wine gallon* standard of 224 *cubic inches* which would have equalled eight *Merchants' pounds* of wheat (i.e. if the wheat had a specific gravity of 0.953 g/cc), or eight *Avoir-du-pois pounds* of wine (i.e. if the wine had a specific gravity of 0.988 g/cc). This capacity of 224 *cubic inches* is taken as the correct wine gallon which remained in use until it was replaced by Queen Anne. The units noted for this system follow those used in the Queen Anne Winchester Wine Gallon System.

## HENRY VII WINCHESTER WINE AND ALE GALLON SYSTEM (1497 - 1601)

This system was based upon the *gallon* capacity standard measuring 268.43 *cubic inches* established by Henry VII. According to Statute 12 Henry VII, 1496, a *pint* of wine and ale was to equal an eighth *gallon* and contain 12 1/2 *Troy ounces* of wheat. This system was altered with the development of new *bushel* and *gallon* standards by Elizabeth I. This table was prepared from capacities given in Skinner 1967: 100 and 105.

## METRIC

549.82	ml	1	<i>Pint</i>

2199.27	ml	4	2	1	<i>Pottle</i>
4398.5377	ml	8	4	2	1 <i>Gallon</i>

## ELIZABETH I WINE AND ALE GALLON SYSTEM (1601 - 1826)

This system was based upon the *gallon* standard measuring 268.97 *cubic inches* established by Elizabeth I as a replacement for the standard established by Henry VII. A second *gallon* standard measuring 270.59 *cubic inches* was apparently incorrectly regarded as the primary standard in 1758 (Skinner 1967: 105). In 1702 William III established a replacement for the Elizabeth I *bushel* standard, but not for the *gallon* standard. This system for wine was abolished in 1707 with the adoption of the Queen Anne Winchester *wine gallon*, and it was totally abolished in 1826 with the adoption of the Imperial Liquid Capacity System.

### QUEEN ANNE WINCHESTER WINE GALLON SYSTEM (pre-1707 - 1826)

This system was possibly in use as early as 1340, but it only became officially adopted by Queen Anne in 1707, and was based upon the *gallon* standard of 231.0 *cubic inches* which may have originally been based upon eight *Avoir-du-pois* pounds of wheat (i.e. if the wheat had a specific gravity of 0.958 g/cc). The official standard actually measured 230.824 *cubic inches*, not the purported 231.0 *cubic inches*. This system was abolished with the adoption of the Imperial Liquid Capacity System; however, it remained in use throughout the 19th century. This table was prepared from capacities given in Good et al. 1813, Doursther 1840, Phillips 1848, Funk 1926, Skinner 1967: 106 and Dresner 1972.

## ALE GALLON SYSTEM ( ? - 1803)

The origin of this system is unknown, and has been presumed to be pre-1340. It appears to have been based upon a beer gallon of approximately 10 *Avoir-du-pois* pounds (i.e. 4.530816 kg). According to Postlethwayt (1774) this system was based upon the *beer gallon* of 282 *cubic inches*, and according to Doursther (1840: 543) and Zupko (1977: 150) it was abolished 1803. This table was prepared from capacities given in Postlethwayt 1774, Doursther 1840, Berriman 1953 and Zupko 1977: 82 and 150.

**BEER GALLON SYSTEM ( ? - 1826)**

The origin of this system is unknown, but a beer system was mentioned in 1660 by Charles II, and it may have been in use during the early 14th century. This system appears to have been based upon a *beer gallon* consisting of approximately 10 *Avoir-du-pois* pounds (i.e. 4.530816 kg). By at least the mid-18th century, the *beer gallon* was defined on the basis of its cubic capacity of 282 *cubic inches*. According to Zupko (1977: 50), ale was also officially measured with this system after 1803. It was officially abolished with the adoption of the Imperial Liquid Capacity System. This table was prepared from capacities given in Postlethwayt 1774, Martin 1794, Good et al. 1813, Funk 1926, Berriman 1953, Johnson 1961, Moody 1960 and Zupko 1977.

## ALE AND BEER GALLON SYSTEM (1688 - 1803)

In 1689 William III and Mary II decreed that 34 *gallons* would constitute a *barrel* of ale and beer (Postlethwayt 1774: Measures), but the exact capacity of this *gallon* remains unknown. Zupko (1977: 150) supplied capacity equivalents for this system, but they remain at odds with equivalents given by Postlethwayt (1774: England).

## IMPERIAL LIQUID CAPACITY SYSTEM (1826 - present)

This system was defined by act of Parliament in 1824 and was officially adopted on 1 January 1826. The *Imperial gallon* was equal to 10 *Avoirdupois pounds* of distilled water weighed in air at the temperature of 62° F at a barometric pressure of 30 *inches* of mercury. It was further defined as 277.274 *cubic inches*, but in 1931-32 the correct cubic capacity was found to be 277.421 *cubic inches*. This table was prepared from capacities given in Doursther 1840, Phillips 1848, Funk 1926, Irwin 1960, Moody 1960, Skinner 1967 and Dresner 1972.

### Linear Systems

Of the six English linear systems identified, two may be considered major systems and the remaining six minor systems (Table 7), with all based upon a single standard.

Table 7. English linear systems and their period of usage.

ENGLISH LINEAR SYSTEMS	PERIOD OF USE
Primary Standard	1305 - 1826
Cloth	?
Wool Cordage	?
Cotton Cordage	?
Linen Cordage	?
Imperial	1826 - 20th C

Of the metrological systems considered within this study, the English Linear System represents the most conservative and stable metrological system yet encountered. Outside of a few terminological variations, this system has remained intact since 1305. It has continually added new metrological units through time, and in 1826 the plethora of units was officially pared to the minimum number in common usage.

ENGLISH OR PRIMARY STANDARD LINEAR SYSTEM (1305 - 1826)

This system was first established by Edward I who defined the *barleycorn*, *inch*, *foot*, *ulna* (*yard*) and *rod*. It was expanded at various times, and finally redefined in 1826 with the adoption of the Imperial Linear System. Base measurement of the *foot* is taken as 30.479449 cm (Doursther 1840: 412). This table was prepared from lengths given in Encyclopaedia... 1798, Good et al. 1813, Doursther 1840: 412 and 466, Skinner 1967 and Zupko 1977: 142.

### IMPERIAL LINEAR SYSTEM (1826 - 20th century)

This system was defined by act of Parliament in 1824 and was officially adopted on 1 January 1826. It was based upon the English Linear System, but changed *poles* to *rods* (dropping the old *rod* of 5 1/2 feet) and added *cable lengths*. This table was prepared from measures given in Doursther 1840 and Zupko 1977: 162.

### Volumetric System

Only one English volumetric system was identified and it was based entirely upon the English Linear System.

#### ENGLISH VOLUME SYSTEM (1305 - present)

This system was based upon the English Linear System. The base measure is the *cubic inch* measuring 16.386163 cc (Doursther 1840:96), which was redefined in 1901 as 16.387162 cc (Judson 1976).

#### METRIC

16.386 mc	1	<i>Cubic Line</i>	
16.386 cc	1000	1	<i>Cubic Inch</i>
28.315 dc	1,728,000	1728	1 <i>Cubic Foot</i>
7.645 ds	46,656,000	46,656	27 1 <i>Cubic Yard</i>

## FRENCH SYSTEMS OF WEIGHTS AND MEASURES

Unlike English systems, French systems were much more provincial in that each city maintained its own separate systems. Many of the larger cities maintained systems which served wider regional needs, and a few systems were adopted by the King to meet those military, academic and bureaucratic needs of the Crown in governing the loose association of French provinces. Two years after the commencement of the French Revolution in 1789, the French National Assembly presented its first official version of a national system of weights and measures. Four years later in 1795, various systems were defined, and after another four years, standards were ratified. However, not until 1840 were the metric systems officially enacted. According to metrological research conducted by Arthur Kennelly (1928), pre-metric weights and measures were still in widespread usage in 1926-27. Earlier provincial metrological units and systems had not been entirely replaced by the Metric System, and older units and systems were preferred by many tradesmen engaged in traditional occupations. From this observation it is inferred that metrological systems are not replaced immediately with the introduction of new systems, rather, both old and new systems function simultaneously for an indeterminate period of time probably exceeding a single generation.

### Dry Weight Systems

Of the six French dry weight systems included within this study, five can be regarded as major systems, with the one remaining system being based upon one of the five major systems (Table 8).

Table 8. French dry weight systems, their known period of usage, and their standard *livre* weights.

FRENCH DRY WEIGHT SYSTEMS	PERIOD OF USE	LIVRE (g)
Marc de Troyes	1350 - 1840	489.41
Pharmaceutique	? - post-1791	367.14
Premier Métrique Pharmaceutique	post-1791 - 1840	512.00
Métrique	1840 - 20th C	-
Métrique Pharmaceutique	1840 - ?	500.00

Three of these major systems were used exclusively for weighing medicines, while the *Système de poids de Marc de Troyes* and *Système métrique de poids* were used for all other commodities.

SYSTEME DE POIDS DE MARC DE TROYES (1350 - 1840)

The *marc* defined by King John of France (1350 - 1364) was 1/50 of the *pile* of Charlemagne, and in 1350 the Système de poids de Marc de Troyes was defined with a set of standards based on Charlemagne's standards. This system was replaced by the Système métrique de poids in 1840. This table was prepared from weights given in Encyclopaedia... 1798, Doursther 1840 and Skinner 1967.

PREMIER SYSTEME METRIQUE DE POIDS PHARMACEUTIQUE (post-1791 - 1840)

This system was used for pharmaceuticals and replaced the older *Système de poids pharmaceutique* sometime after 1791 when the French National Assembly announced the *Système métrique de poids*. It was brought into use during the initial years of the French Revolution and was eventually replaced by a revised *Système métrique de poids pharmaceutique* enacted by law in 1837, and was prohibited from use after 1840. This table was prepared from weights given in Doursther 1840: 235.

### SYSTEME METRIQUE DE POIDS (1840 - present)

This system was first officially presented by the French National Assembly in 1791. It was defined in 1795, and standards were ratified in 1799. However, older weight systems were not officially abolished until 1837 when a law was passed which levied a fine on anyone using these older systems after 1840. Even with legislation, older weight systems were still being used in France well into the 20th century. In 1799 the *kilogram* standard was established as the weight of a *decistere* (1000 cc) of water at normal atmospheric pressure at 4° C (Klein 1974: 199-200), and one *gram* of water equalled one *cubic centimeter* or one *milliliter*. This table was prepared from weights given in Doursther 1840.

### Liquid Weight Systems

No examples of French liquid weight systems were encountered.

### Dry Capacity Systems

As mentioned at the beginning of this discussion of French weights and measures, every city utilized its own units and systems. For dry capacity the plethora of units and systems has yet to be fully comprehended. It would appear that every city had dry capacity units to be used for agricultural grain crops, and some cities appear to have used separate systems for wheat and oats. Paris had one system for grain and lime, and separate systems for oats, coal, charcoal and salt. Of the 40 or so city systems reported by Horace Doursther (1840), only a dozen of the major commercial city systems are reproduced in this study. General knowledge of these systems is sparse, and a lifetime would have to be devoted to the study of French city metrological systems before one could fully comprehend the multitude of dry capacity systems in use during the 15th - 19th centuries. Such a task is obviously beyond the scope of this study.

Suffice to note that pre-19th-century French dry capacity measures were exceedingly complex and communally derived. Metrological units were often identified by identical terms in each of the major cities, but their capacities varied tremendously. Standards were maintained by city governments and merchants' guilds, and in many cities the regulation of weights and measures was quite strict. However, inter-city commerce was often conducted with inaccurate measures, and the size variability of any given unit was great. Not until the *Système de capacité du Boisseau usuel pour les matières sèches* was established in 1812 was a nationwide system available, and it was quickly replaced by the *Système métrique de capacité pour les matières sèches et les liquides* in 1840.

## Liquid Capacity Systems

As with French dry capacity systems, liquid capacity systems were exceedingly numerous, with many cities having separate measures for wine, eau de vie, oil, etc. Only a sample of these diverse systems is presented for a few of the major commercial centers. With the development of the *Système métrique de capacité pour les matières sèches et les liquides*, a single system for both dry and liquid capacities was established throughout France.

### Linear Systems

Of the eight French linear systems included within this study, four can be regarded as major national systems, two were used for cloth measurement and were based upon one of the national systems, and two were city systems used for land and construction measurements (Table 9).

Table 9. French linear systems and their period of usage.

FRENCH LINEAR SYSTEMS	PERIOD OF USE
Ancien pied du roi	ca. 8th C - 1668
Pied du roi	1668 - 1840
Pied de St-Hubert de Liège	? - 1840
Pied de St-Lambert de Liège	? - 1840
Pied usuel	1812 - 1840
Métrique	1840 - 20th C

The Systèmes de longueur du pied du roi were originally based upon the *aune* standard used for cloth measurement, but in 1668 the standard became a newly defined *toise*. The reasons for the use and survival of the Liège linear systems is not known, but their existence does indicate that regional and city measures were preferred over the royal systems by some of the trades.

ANCIEN SYSTEME DE LONGUEUR DU PIED DU ROI (ca. 8th century - 1668)

Half of the *Hashimi cubit* of 25.56 inches (64.9 cm) became the *Frankish pied* of Charlemagne, 771 - 814 (Skinner 1967: 88-89). As defined, this system was based upon the *aune* standard of 1554 established by François I (Machabey 1969). In 1668 a new *toise* standard was created which measured 11 mm shorter than the earlier *toise* standard (the original *aune* standard was retained after 1668, but all other measures were subsequently made in relation to the new *toise* standard, see *Système de longueur du pied du roi*). This table was prepared from measures given in Doursther 1840 and Machabey 1969.

### SYSTEME DE LONGUEUR DU PIED DU ROI (1668 - 1840)

This system was based upon the Ancien système de longueur du pied du roi, but its measures were based upon the new *toise* standard of 1668, except for the *aune* which remained unchanged. This table was based upon measures given in Doursther 1840, Skinner 1967 and Machabey 1969.

4.67 m	16,000	1600	160	16	1	<i>Petite Verge</i>

## SYSTEME METRIQUE DE LONGUEUR OU DU PIED USUEL (1812 - 1840)

This system was established by Napoleon in 1812 as a compromise between the *Système de longueur du pied du roi* and the *Système métrique de longueur*. In this system a *pied usuel* equalled  $1/3$  *meter*. It was abolished by law in 1837 and was prohibited from use after 1840. This table was prepared from measures given in Doursther 1840.

## METRIC

2.315	mm	1	<i>Ligne</i>			
2.778	cm	12	1 <i>Pouce</i>

2.0	m	864	72	6	1.666...	1 <i>Toise Usuelle</i>

## SYSTEME METRIQUE DE LONGUEUR (1840 - present)

This system was first officially presented by the French National Assembly in 1791. The system was defined in 1795, and standards were ratified in 1799. The standard *meter* in 1795 was defined as the ten-millionth part of the arc of meridian from Pole to Equator (Klein 1974: 123). The earlier *Système de longueur du pied du roi* and the *Système métrique de longueur ou du pied usuel* were abolished by law in 1837 and the *Système métrique de longueur* was put into use in 1840. This table was prepared from measures given in Doursther 1840.

## METRIC

### Superficial Systems

Six French superficial systems have been identified, including four major national systems and two city systems (Table 10).

Table 10. French superficial systems and their period of usage.

FRENCH SUPERFICIAL SYSTEMS	PERIOD OF USE
Ancien pied du roi	ca. 8th C - 1668
Pied du roi	1668 - 1840
Pied de St-Lambert de Liège	? - 1840
Bois de Liège	? - 1840
Pied usuel	1812 - 1840
Métrique	1840 - 20th C

All systems except one were based upon historically identified linear systems. The single exception was the *Système de surface de Liège pour le bois* for which no comparable linear system has been located.

**ANCIEN SYSTEME DE SURFACE DU PIED DU ROI (ca. 8th century - 1668)**

This system is postulated as the square measures of the Ancien système de longueur du pied du roi, following terminology for the Système de surface du pied du roi.

METRIC

### Volumetric Systems

Four French volumetric systems have been identified and all were based upon related linear systems.

#### ANCIEN SYSTEME DES VOLUMES DU PIED DU ROI (ca. 8th century - 1668)

This system was based upon the Ancien système de longueur du pied du roi and follows terminology from the Système de longueur du pied du roi.

##### METRIC

0.00675	mc	1	<i>Point Cube</i>				
11.666	mc	1728		1	<i>Ligne Cube</i>		
20.168	cc	2,985,984	1728	1	<i>Pouce Cube</i>		
34.834	dc	$5.160... \times 10^9$	2,985,984	1728		1	<i>Pied Cube</i>
7.530	s	$1.115... \times 10^{12}$	$6.450... \times 10^8$	373,248	216	1	<i>Toise Cube</i>

#### SYSTEME DES VOLUMES DU PIED DU ROI (1668 - 1840)

This system was based upon the Système de longueur du pied du roi, and this table was prepared from measures given in Doursther 1840.

##### METRIC

0.00664	mc	1	<i>Point Cube</i>				
11.479	mc	1728		1	<i>Ligne Cube</i>		
19.836	cc	2,985,984	1728	1	<i>Pouce Cube</i>

8.0 s	$6.450... \times 10^8$	373,248	216	1 <i>Toise Cube</i>

SYSTEME METRIQUE DES VOLUMES (1840 - present)

This system was based upon the Système métrique de longueur. In 1795 the *stere* was defined as one *cubic meter*, and later in 1799, one *cubic centimeter* of water at normal atmospheric pressure at 4° C was defined as equal to one *milliliter* or one *gram*. This table was prepared from measures given in Doursther 1840.

METRIC

1.0 mc	1	<i>Cubic Millimeter (mc)</i>

## AMERICAN SYSTEMS OF WEIGHTS AND MEASURES

When Europeans emigrated to North America, they packed up their material culture and brought along traditional societal values. Included within their cultural baggage were contemporary and anachronistic metrological units and systems. These metrological values became regionalized and codified by each of the colonies, until a few were eventually sorted out and codified as national systems. These resultant national systems were originally derived from English systems, albeit with a few deletions. No attempt has been made to identify the various communal and colonial systems which may have existed prior to the Revolutionary War. Rather, only those systems that eventually emerged as national systems have been reported.

### Dry Weight Systems

Three American dry weight systems have been identified, including two major systems and a single remaining system based upon one of the major systems.

#### AMERICAN TROY POUND WEIGHT SYSTEM (1497 - present)

This is the same system used in England. It was officially adopted in 1828 from an "exact" copy of the 1758 English standard which purportedly weighed 373.202021511 g (Doursther 1840: 214 and Judson 1976). After 1844 the *Troy pound* would have been 373.242 g in relationship to the *Avoirdupois pound* measured at that time.

#### AMERICAN APOTHECARY WEIGHT SYSTEM (post-1497 - 20th century)

This is the same system used in England and identified as the Apothecary Weight System.

### AMERICAN AVOIRDUPOIS POUND WEIGHT SYSTEM (1582 - present)

This is basically the same system used in England without the *scruple* and *stone*. It was officially adopted in 1832 as 7000/5760 *Troy pounds*. The actual weight is unknown, but 7000/5760 of the 1758 English *Troy* standard would have been 453.544 g. However, the English *Avoirdupois pound* standard measured in 1844 was 453.59265 g, while the American *Avoirdupois pound* after 1893 was 453.5924277 g and after 1959 was 453.59237 g. This table was prepared from weights given in Doursther 1840 and Judson 1976.

#### METRIC

0.0648	g	1	<i>Troy Grain</i>								
1.772	g	27.34375	1	<i>Dram</i>							
28.350	g	437.5	16	<i>Avoirdupois Ounce</i>

12.70	kg	196,000	7168	448	28	<i>Quarter</i>					
45.36	kg	700,000	25,600	1600	100	3.571...	<i>Short Hundredweight</i>				
50.80	kg	784,000	28,672	1792	112	4	1.12	<i>Hundredweight</i>			
907.18	kg	14,000,000	512,000	32,000	2000	71.428...	20	17.857...	<i>Short Ton</i>		
1.016	mt	15,680,000	573,440	35,840	2240	80	22.4	20	1.12	<i>Long Ton</i>	

### Liquid Weight Systems

No examples of American liquid weight systems were encountered.

### Dry Capacity System

#### AMERICAN DRY CAPACITY SYSTEM (1702 - present)

This system is based upon the English system identified as the William III Winchester Corn Capacity System and was based upon the *bushel* measuring 2150.42 *cubic inches*. This table was prepared from measures given in Doursther 1840, Skinner 1967 and Judson 1976.

#### METRIC

550.58	m1	1	<i>Pint</i>		
1101.16	m1	2	1	<i>Quart</i>	
8.809	1	16	8	1	<i>Peck</i>
35.237133	1	64	32	4	1 <i>Bushel</i>

### Liquid Capacity System

#### AMERICAN LIQUID CAPACITY SYSTEM (1707 - present)

This system is based upon the English system identified as the Queen Anne Winchester Wine Gallon System and was based upon the gallon measuring 231.0 *cubic inches*. This table was prepared from measures given in Doursther 1840, N.C.R.P. 1883, Funk 1926, Asimov 1960, Skinner 1967 and Judson 1976.

### Linear System

#### AMERICAN LINEAR SYSTEM (1305 - present)

This is the same system used in England identified as the English or Primary Standard Linear System and based upon the *yard* of 91.438348 cm. After 1893 the *yard* was recognized as  $3600/3937$  m, or 91.440183 cm, and after 1959 it was 91.44 cm (Doursther 1840 and Judson 1976).

### Superficial System

#### AMERICAN AREA SYSTEM (1305 - present)

This is the same system used in England and identified as the English Area System.

### Volumetric System

#### AMERICAN VOLUME SYSTEM (1305 - present)

This is the same system used in England and identified as the English Volume System.

## CANADIAN SYSTEMS OF WEIGHTS AND MEASURES

As in America, European settlers in Canada imported contemporary and anachronistic metrological units and systems from their homelands. With the development of political organizations within Canada, various regions adopted English and/or French units and systems as their own colonial or provincial units and systems. For example, the General Assembly of Nova-Scotia formally adopted contemporary English metrological systems in 1758, while Quebec adopted French units and systems in 1676 and English units and systems in 1799.

Once systems were adopted, provinces were subsequently reluctant to revise or replace them. Even when parent countries adopted new systems, the colonies and provinces continued to use their earlier systems. Thus, most Canadian provinces retained their Winchester systems until 1873 when, after Confederation, the Imperial system formally became the national system.

No unique or new metrological systems were created by any of the Canadian colonies or provinces. All systems in common usage, as well as those codified in provincial law, were adopted from previously existing systems within either France or England. Lower Canada utilized a wide variety of local French units, even after 1676 when specific units and systems were officially mandated; and it was not until 1799, almost four decades after the end of the Seven Years' War, that Lower Canada officially adopted both English and French units and systems. Nova-Scotia (1758), New Brunswick (1786), Prince Edward Island [Island of St. John] (1795) and Upper Canada (1792) adopted English systems in the late 18th century; while Newfoundland (1834) and British Columbia (1867) adopted English systems in the mid-19th century; and Manitoba, Alberta and Saskatchewan adopted the Canadian-codified English systems when they joined Confederation in the late 19th and early 20th centuries.

Exact units and systems approved by provincial and federal assemblies and parliaments have been codified in specific acts on weights and measures (see Appendix A), as well as in various acts regulating commodity duties, markets and commercial products (e.g. bread, butter, beef, flour, grain, fish, etc.).

In 1871, the Parliament of Canada legalized the use of French Metric systems of weights and measures throughout Canada, and not until 1873 were the use of English systems officially defined in order to establish uniform systems for the entire Dominion of Canada. For Quebec, however, additional French linear and superficial units were also retained for land measure. Until 1873, metrological units and systems in Canada were defined by provincial statutes and laws.

### Dry Weight Systems

All dry weight systems legally adopted within Canada were English dry weight systems, except for the French Metric weight system adopted by the Dominion of Canada in 1871 (following weights provided in Canadian legal statutes, 1676-1896; see Appendix A).

#### British Columbia, Including the Colonies of Vancouver Island and British Columbia (1858 - 1871)

Avoirdupois Pound Weight System (adopted 1867).  
 Troy Pound Weight System (adopted 1867).  
 Apothecary Weight System (adopted 1867).

#### New Brunswick (1784 - 1867)

Avoirdupois Pound Weight System (adopted 1786).  
 Troy Pound Weight System (adopted 1786).  
 After 1803, a *firkin* of butter was to weigh 60 *Avoirdupois* pounds.

After 1853, the following commodities were regulated by weight:

<i>Bushel</i> of wheat, Indian corn	=	60	<i>Avoirdupois</i>	pounds
" " of rye, other grains, edible roots	=	56	"	"
" " of barley, buckwheat	=	50	"	"
" " of timothy seed	=	40	"	"
" " of oats	=	36	"	"
<i>Ton</i> of coal	=	2240	"	"

After 1866, the *hundredweight* was 100 *Avoirdupois* pounds and the *ton* was 2000 *Avoirdupois* pounds.

#### Newfoundland (1832 - 1900)

Avoirdupois Pound Weight System (adopted 1834).  
 Troy Pound Weight System (adopted 1834).  
 After 1864, the following commodities were regulated by weight:

<i>Bushel</i> of wheat, peas, beans, edible roots	=	60	<i>Avoirdupois</i>	pounds
" " of Indian corn	=	57	"	"
" " of rye	=	56	"	"
" " of flax seed	=	50	"	"
" " of barley	=	48	"	"
" " of hemp seed	=	44	"	"
" " of oats	=	38	"	"
<i>Ton</i> of coal	=	2240	"	"
<i>Barrel</i> of pork, beef, jowls	=	200	"	"
" " of flour, corn, oatmeal	=	196	"	"
<i>Half-barrel</i> of pork, beef, jowls	=	100	"	"
" " of flour, corn, oatmeal	=	98	"	"
<i>Bag</i> of biscuits	=	112	"	"
<i>Half-bag</i> of biscuits	=	56	"	"

## Nova Scotia (1758 - 1867)

Avoirdupois Pound Weight System (adopted 1758).

Troy Pound Weight System (adopted 1758).

After 1792, the following commodities were regulated by weight:

<i>Bushel</i> of peas	=	60	<i>Avoirdupois pounds</i>
" " of wheat, Indian corn	=	58	" "
" " of rye	=	56	" "
" " of barley	=	48	" "
" " of oats	=	34	" "

After 1794, beef and pork were to be sold by the *barrel* of 200 *Avoirdupois pounds* and the *half barrel* of 100 *Avoirdupois pounds*.

After 1796, a *sack* of meal or flour was to weigh 2 *hundredweights*, 2 *quarters* or 280 *Avoirdupois pounds*.

After 1850, flour and meal were to be sold by the *barrel* of 196 *Avoirdupois pounds* and the *half barrel* of 98 *Avoirdupois pounds*.

After 1864, the *hundredweight* was 100 *Avoirdupois pounds* and the *ton* was 2000 *Avoirdupois pounds*.

## Prince Edward Island or the Island of St. John (1773 - 1873)

Avoirdupois Pound Weight System (adopted 1795).

Troy Pound Weight System (adopted 1795).

After 1837, the following commodities were regulated by weight:

<i>Bushel</i> of peas, beans	=	60	<i>Avoirdupois pounds</i>
" " of wheat	=	58	" "
" " of Indian corn	=	57	" "
" " of rye	=	56	" "
" " of barley	=	48	" "
" " of oats	=	36	" "

After 1869, the following commodities were regulated by weight:

<i>Bushel</i> of potatoes	=	65	<i>Avoirdupois pounds</i>
" " of turnips, carrots, beets	=	60	" "
" " of parsnips	=	56	" "

## Quebec or Lower Canada (1663 - 1867)

Avoirdupois Pound Weight System (adopted 1799).

Troy Pound Weight System (adopted 1799).

After 1836, a *ton* of coal was to weigh 20 *hundredweight* or 2240 *Avoirdupois pounds*.

## Upper Canada (1791 - 1867)

Avoirdupois Pound Weight System (adopted 1792).

Troy Pound Weight System (adopted 1792).

After 1835, the following commodities were regulated by weight:

<i>Bushel</i> of wheat, peas, timothy seed, clover seed	=	60	<i>Avoirdupois pounds</i>
---	---	----	---------------------------

<i>Bushel</i> of rye, Indian corn	=	56	<i>Avoirdupois pounds</i>
" " of beans	=	50	" "
" " of barley	=	48	" "
" " of oats	=	34	" "
After 1853, the following commodities were regulated by weight:			
<i>Bushel</i> of beans	=	60	<i>Avoirdupois pounds</i>
" " of timothy seed, buck-wheat	=	48	" "

**Province of Canada, Including Upper and Lower Canada (1848 - 1867)**

After 1859, the following commodities were regulated by weight:

<i>Bushel</i> of wheat, peas, beans, edible roots, clover seeds	=	60	<i>Avoirdupois pounds</i>
" " of Indian corn, rye, salt	=	56	" "
" " of flax seed	=	50	" "
" " of barley, timothy seed, buck-wheat	=	48	" "
" " of hemp seed	=	44	" "
" " of castor beans	=	40	" "
" " of malt	=	36	" "
" " of oats	=	34	" "
" " of dried peaches	=	33	" "
" " of dried apples	=	22	" "
" " of blue grass seed	=	14	" "

After 1859, the *hundredweight* was 100 *Avoirdupois pounds* and the *ton* was 2000 *Avoirdupois pounds*.

After 1860, hay and straw were regulated by weight:

<i>Ton</i> of timothy, clover, other hay, straw	=	2000	<i>Avoirdupois pounds</i>
<i>Bundle</i> of timothy, clover, other hay with a withe band	=	16	" "
" " of timothy, clover, other hay with a timothy band	=	15	" "
" " of straw	=	12	" "

**Dominion of Canada (1867 - 1900)**

**Metric Weight System (adopted 1871).**

- the *metric ton* was known in Canada as a *millier*.

**Avoirdupois Pound Weight System (adopted 1873).**

**Troy Pound Weight System (adopted 1873).**

After 1873, the following commodities were regulated by weight:

<i>Bushel</i> of wheat, peas, beans, edible roots, clover seed	=	60	<i>Avoirdupois pounds</i>
" " of Indian corn, rye, salt	=	56	" "
" " of flax seed	=	50	" "
" " of barley, timothy seed, buck-wheat	=	48	" "
" " of hemp seed	=	44	" "

<i>Bushel</i> of castor beans	=	40	<i>Avoirdupois pounds</i>
" " of malt	=	36	" "
" " of oats	=	34	" "
" " of dried peaches	=	33	" "
" " of dried apples	=	22	" "
" " of blue grass seed	=	14	" "

After 1885, a *bushel* of bituminous coal was to weigh 70 *Avoirdupois pounds*.

After 1886, hay and straw were regulated by weight:

<i>Bundle</i> of timothy, clover, other hay with a withe band	=	16	<i>Avoirdupois pounds</i>
" " of timothy, clover, other hay with a timothy band	=	15	" "
" " of straw	=	12	" "

#### Liquid Weight Systems

No examples of Canadian liquid weights systems were encountered.

#### Dry Capacity Systems

Throughout Canada, except for Quebec, English dry capacity systems were adopted. Quebec adopted English systems in 1799, but certain specified French units were allowed to remain in use until the Uniform Weights and Measures Act was adopted by the Dominion of Canada in 1873. Unfortunately, the exact size and relationships of the French units used in Quebec remain unknown. The only legally defined units which can be attributed to French units were the *bushel* and *chaldron* used to measure coal after 1836. In 1871, the Dominion of Canada also adopted the French Metric Dry and Liquid Capacity System. Information on capacity units and systems was obtained from Canadian legal statutes, 1676 - 1896 (see Appendix A).

#### British Columbia, Including the Colonies of Vancouver Island and British Columbia (1858 - 1871)

Imperial Dry Capacity System (adopted 1867).

#### New Brunswick (1784 - 1867)

William III Winchester Corn Capacity System (adopted 1786).

After 1793, a *hogshead* of lime was to have a dry capacity of 100 gallons.

After 1830, the following commodities were regulated by dry capacity:

*Chaldron* of coal = 12 *tubs* or 48 *bushels*.

*Tub* of coal, salt = 4 bushels.

NOTE: The measure *tub* has not been used in any metrological system yet identified. It may represent a unique local metrological unit for New Brunswick.

#### Newfoundland (1832 - 1900)

Imperial Dry Capacity System (adopted 1834).

- 3 bushels = 2 1/2 heaped bushels.

- Hogshead of coal = 63 gallons.

After 1896, a *barrel* of fresh herring was to have a dry capacity of 32 gallons.

#### Nova Scotia (1758 - 1867)

William III Winchester Corn Capacity System (adopted 1758).

After 1762, a *barrel* of pickled fish was to have a dry capacity of 31 1/2 gallons.

After 1789, a *tierce* of salmon was to have a dry capacity of 42 gallons and a *barrel* of pickled fish was to be 30 gallons.

After 1792, a *hogshead* of lime was to have a dry capacity of 96 gallons or 8 heaped bushels.

After 1794, beef and pork were to be sold by the *barrel* of 30-31 gallons and the *half barrel* of 15 1/2-16 gallons.

After 1798, pickled fish could also be sold by the *half barrel* of 16 gallons, the *quarter barrel* of 8 gallons and the *eighth barrel* of 4 gallons.

After 1828, pickled fish was to be sold by the *tierce* of 45-46 gallons, *barrel* of 29-30 gallons and the *half barrel* of 15 gallons.

After 1830, beef and pork were to be sold by the *barrel* of 27-28 gallons and the *half-barrel* of 14-15 gallons.

#### Prince Edward Island or the Island of St. John (1773 - 1873)

William III Winchester Corn Capacity System (adopted 1795).

After 1833, potatoes and turnips were to be sold by the *bushel*, with 3 bushels = 2 1/2 heaped bushels.

After 1841, potatoes and turnips were to be sold by the *bushel*, with 2 1/2 bushels = 2 heaped bushels.

After 1846, a *barrel* of lime was to have a dry capacity of 3 bushels.

After 1856, edible roots were to be sold by the *bushel*, with 2 5/8 bushels = 2 heaped bushels.

#### Quebec or Lower Canada (1663 - 1867)

In 1676, the following French or Paris measures were officially adopted:

- *Comme minot*
- *Demi minot*
- *Boisseau*

- *Pot*
- *Pinte*

Their precise capacities remain unknown.

In 1799, the English Dry Capacity System adopted was the William III Winchester Corn Capacity System. "Canadian measures" also retained were the *poisson*, *pot*, *half minot* and *minot* (precise capacities unknown). These Canadian measures may have come from the *Système de capacité pour les matières sèches de Paris employé pour les grains et la chaux*.

After 1836, coal was to be sold by the *chaldron* of 36 *bushels* (58.64 *feet*<sup>3</sup>) and the *bushel* of 2814 9/14 *inches*<sup>3</sup> (46.120738 liters). This bushel is approximately equal to the French *boisseau* used in the *Système de capacité pour les matières sèches de Paris employé pour le charbon* (i.e. the *boisseau* of 45.54 liters), while the *chaldron* does not equate with any coal measure yet identified; it is roughly equivalent to 6 *minots* of the *Système de capacité pour les matières sèches de Paris employé pour le charbon* (i.e. the *chaldron* = 1660.3466 liters, while 6 *minots* = 1639.2 liters). In the French version of the Lower Canada statute for 1836 (i.e. 6 William IV, Chapter 36, Section 2), the *chaldron* is translated as a *voie*. However, the *voie* of the *Système de capacité pour les matières sèches de Paris employé pour le charbon* is 4098.00 liters, some 2 1/2 times larger than the *chaldron*. Presumably, the coal *bushel* and *chaldron* of Lower Canada, post-1836, correspond to some as yet unidentified, pre-existing French coal measures.

#### Upper Canada (1791 - 1867)

William III Winchester Corn Capacity System (adopted 1792).

#### Province of Canada, Including Upper and Lower Canada (1848 - 1867)

After 1859, a *chaldron* of coal was to have a dry capacity of 36 *Imperial bushels*. NOTE: This is an interesting adoption of a metrological unit (i.e. an English Imperial measure) by a province which had yet to adopt the entire metrological system. The Imperial Dry Capacity System was not adopted by either Upper or Lower Canada until its adoption by the Dominion of Canada in 1873.

#### Dominion of Canada (1867 - 1900)

Metric Dry and Liquid Capacity System (adopted 1871).

- the units *millilitre* and *huitime* were not adopted.

Imperial Dry Capacity System (adopted 1873).

Until 1880, the *bushel* of the William III Winchester Corn Capacity System was allowed to continue in use.

After 1879, a *barrel* = 25 *gallons*.

### Liquid Capacity Systems

All liquid capacity systems adopted within Canada were English liquid capacity systems, except for the *Système métrique français de capacité pour les matières sèches et les liquides* adopted by the Dominion of Canada in 1871 (following liquid capacities provided in Canadian legal statutes, 1676-1896; see Appendix A).

#### British Columbia, Including the Colonies of Vancouver Island and British Columbia (1858 - 1871)

Imperial Liquid Capacity System (adopted 1867).

#### New Brunswick (1784 - 1867)

Queen Anne Winchester Wine Gallon System (adopted 1786).

#### Newfoundland (1832 - 1900)

Imperial Liquid Capacity System (adopted 1834).

#### Nova Scotia (1758 - 1867)

Queen Anne Winchester Wine Gallon System (adopted 1758).

#### Prince Edward Island or the Island of St. John (1773 - 1873)

Queen Anne Winchester Wine Gallon System (adopted 1795).

#### Quebec or Lower Canada (1663 - 1867)

Queen Anne Winchester Wine Gallon System (adopted 1799).

#### Upper Canada (1791 - 1867)

Queen Anne Winchester Wine Gallon System (adopted 1792).

#### Province of Canada, Including Upper and Lower Canada (1848 - 1867)

No new systems were adopted, rather the Queen Anne Winchester Wine Gallon System continued in use.

#### Dominion of Canada (1867 - 1900)

Metric Dry and Liquid Capacity System (adopted 1871).

- the units *millilitre* and *huitime* were not adopted.

Imperial Liquid Capacity System (adopted 1873).

Until 1880, the *gallon* of the Queen Anne Winchester Wine Gallon System was allowed to continue in use.

## Linear Systems

Throughout Canada, except for Quebec, English linear systems were adopted. Quebec adopted the English or Primary Standard Linear System and the French *Système de longueur du pied du roi* in 1799, and after the Uniform Weights and Measures Act was adopted by the Dominion of Canada in 1873, Quebec retained only three linear units for land measurement. In 1871, the Dominion of Canada also adopted the French *Système métrique du longueur*. Information on linear units and systems was obtained from Canadian legal statutes, 1676 - 1896 (see Appendix A).

### British Columbia, Including the Colonies of Vancouver Island and British Columbia (1858 - 1871)

Imperial Linear System (adopted 1867).

### New Brunswick (1784 - 1867)

English or Primary Standard Linear System (adopted 1786).

### Newfoundland (1832 - 1900)

Imperial Linear System (adopted 1834).

### Nova Scotia (1758 - 1867)

English or Primary Standard Linear System (adopted 1758).

After 1792, bricks had to measure 8 *inches* X 4 *inches* X 2 *inches*.

After 1816, large bricks had to measure 9 *inches* X 4  $\frac{3}{8}$  *inches* X 2  $\frac{1}{2}$  *inches*, while small bricks had to measure 8  $\frac{1}{4}$  *inches* X 4 *inches* X 2 *inches*.

### Prince Edward Island or the Island of St. John (1773 - 1873)

English or Primary Standard Linear System (adopted 1795).

### Quebec or Lower Canada (1663 - 1867)

In 1676, the *aulne* [i.e. *aune*] and *demie aulne* [i.e. *demi aune*] were officially adopted. Unfortunately, the precise length of these units remains unknown.

In 1799, the English or Primary Standard Linear System and the French *Système de longueur du pied du roi* were adopted.

### Upper Canada (1791 - 1867)

English or Primary Standard Linear System (adopted 1792).

Province of Canada, Including Upper and Lower Canada (1848 - 1867)

No new systems were adopted, rather the English or Primary Standard Linear System and the French *Système de longueur du pied du roi* continued in use.

Dominion of Canada (1867 - 1900)

Metric Linear System (adopted 1871).

Imperial Linear System (adopted 1873).

After 1873, only three French linear units were allowed to be used for land measure in parts of Quebec under seigniorial tenure:

*French or Paris foot* (i.e. *Pied du roi*) = 12.79 inches  
(32.487 cm).

*Perch* = 18 *French feet* (5.848 meters).

*Arpent* = 180 *French feet* (58.476 meters).

### Superficial Systems

Throughout Canada, except for Quebec, the English Area System was the only superficial system adopted. Quebec adopted the English Area System and the French *Système de surface du pied du roi* in 1799, and after the Uniform Weights and Measures Act was adopted by the Dominion of Canada in 1873, Quebec retained only two area units for land measurement. In 1871, the Dominion of Canada also adopted a modified or shortened version of the French *Système métrique du surface*. Information of superficial units and systems was obtained from Canadian legal statutes, 1676 - 1896 (see Appendix A).

British Columbia, Including the Colonies of Vancouver Island and  
British Columbia (1858 - 1871)

English Area System (adopted 1867).

New Brunswick (1784 - 1867)

English Area System (adopted 1786).

Newfoundland (1832 - 1900)

English Area System (adopted 1834).

Nova Scotia (1758 - 1867)

English Area System (adopted 1758).

Prince Edward Island or the Island of St. John (1773 - 1873)

English Area System (adopted 1795).

**Quebec or Lower Canada (1663 - 1867)**

English Area System (adopted 1799).

French *Système de surface du pied du roi* (adopted 1799).

**Upper Canada (1791 - 1867)**

English Area System (adopted 1792).

**Province of Canada, Including Upper and Lower Canada (1848 - 1867)**

No new area systems were adopted, rather the English Area System and the French *Système de surface du pied du roi* continued in use.

**Dominion of Canada (1867 - 1900)****CANADIAN METRIC SYSTEM (adopted AD 1871 - present)****METRIC**

1	ca	1	<i>Centiare (ca)</i>		
100	ca	100	1	<i>Are (a)</i>	
10	a	1000	10	1	<i>Decare (da)</i>
100	a	10,000	100	10	1 <i>Hectare (ha)</i>

In 1873, the English Area System was officially adopted as the superficial system for the Dominion of Canada. Only two additional area units were allowed to be used for land measure in parts of Quebec under seigniorial tenure:

*Perch* = 324 *French feet*<sup>2</sup> (34.194 ca).

*Arpent* = 32,400 *French feet*<sup>2</sup> (34.194 a).

**Volumetric Systems**

No examples of Canadian volumetric systems were encountered, but use of both English and French volumetric systems could be expected.

APPENDIX A. ACTS AND ORDINANCES REGULATING WEIGHTS AND MEASURES USED  
WITHIN CANADA AND ITS PROVINCES DURING THE 17TH THROUGH  
19TH CENTURIES

- QUEBEC                   Ordonnances des Intendants et Arrêts portant  
Réglements du Conseil Supérieur de Québec  
1676  
Reglemens, Généraux pour la Police, Section 4.
- QUEBEC                   Complément des Ordonnances et Jugements des  
Gouverneurs et Intendants du Canada  
1730  
Ordonnances de Gouverneurs et Intendants du  
Canada, sur la Voirie et la Police, Ordonnance  
qui ordonne à tous Marchands et Négociants de  
Montréal de faire marquer et étalonner leurs  
Poids et Mesures, et qui enjoint au  
Lieutenant-Général de les vérifier tous les six  
mois, à peine de 10 lbs. d'amende; du  
vingt-deuxième Juillet, mil sept cent trente.
- QUEBEC                   Complément des Ordonnances et Jugements des  
Gouverneurs et Intendants du Canada  
1732  
Ordonnances de Gouverneurs et Intendants du  
Canada, sur la Voire et la Police, Ordonnance qui  
enjoint à tous négociants, marchands, boulangers,  
bouchers, cabaretiers, regattiers et tous autres,  
de faire marquer et étalonner leurs Poids et  
Mesures au greffe de la Prévôté de Québec, sous  
peine de 10 lbs. d'amende; du neuvième Août, mil  
sept cent trente-deux.
- NOVA SCOTIA           Acts of the General Assembly of the Province of  
Nova-Scotia  
1758  
Act 32 George II, Chapter 16, An Act for  
preventing frauds by Butchers and Fishmongers.
- NOVA SCOTIA           Acts of the General Assembly of the Province of  
Nova-Scotia  
1758  
Act 32 George II, Chapter 21, An Act relating to  
the Assize of Bread, and for ascertaining the  
standard of Weights and Measures, Sections 1-3,  
abridged by Title 104.
